(Received 3 August 1998; revised manuscript received 2 October 1998)

Using a “reduced” renormalization method, we study the critical behavior for intermittency in two-coupled one-dimensional (1D) maps. Two fixed points of the reduced renormalization operator are found. They all have common relevant eigenvalues associated with scaling of the control parameter of the uncoupled 1D map. However, the relevant “coupling eigenvalues” associated with coupling perturbations vary depending on the fixed points. We also study the intermittency for a dissipatively coupled case and confirm the renormalization results. Finally, the results of the two coupled 1D maps are extended to many globally coupled 1D maps, in which each 1D map is coupled to all the other ones with equal strength. [S1063-651X(99)11203-0]

I. INTRODUCTION

An intermittent transition to chaos in the 1D map occurs in the vicinity of a saddle-node bifurcation [1]. Intermittency just preceding a saddle-node bifurcation to a periodic attractor is characterized by the occurrence of intermittent alternations between laminar and turbulent behaviors. Scaling relations for the average duration of laminar behavior in the presence of noise have been first established [2] by considering a Langevin equation describing the map near the intermittency threshold and using Fokker-Plank techniques. The same scaling results have been later found [3] by using the same renormalization-group equation [4] for period doubling with a mere change of boundary conditions appropriate to a saddle-node bifurcation.

Recently, efforts have been made to generalize the scaling results of period doubling for the 1D map to coupled 1D maps [5–11], which are used to simulate spatially extended systems with effectively many degrees of freedom [12]. It has been found that the critical scaling behaviors of period doubling for the coupled 1D maps are much richer than those for the uncoupled 1D map [8–11]. These results for the abstract system of the coupled 1D maps are also confirmed in the real system of the coupled oscillators [13]. In a similar way, the scaling results of the higher period p-tuplings (p = 3, 4, . . .) in the 1D map are also generalized to the coupled 1D maps [14]. Here we are interested in another route to chaos via intermittency in coupled 1D maps. Using a reduced renormalization method, we extend the scaling results of intermittency for the 1D map to coupled 1D maps.

This paper is organized as follows. In Sec. II we introduce two-coupled 1D maps and discuss their symmetry. Bifurcations associated with stability of periodic orbits are also discussed there. In Sec. III we employ the “reduced” renormalization method [10] developed for period doubling in coupled 1D maps and study the critical behavior for intermittency in two-coupled 1D maps. We thus find two fixed points of the reduced renormalization operator. They have the relevant eigenvalues associated with scaling of the control parameter of the uncoupled 1D map as common ones.

II. TWO-COUPLED 1D MAPS

After briefly reviewing the intermittency in case of the 1D map, we introduce two-coupled 1D maps and discuss their symmetry. Bifurcations associated with stability of periodic orbits are also discussed.

We first recapitulate the intermittent transition to chaos [1–3] in a 1D map with one control parameter $A$, $X_{t+1} = u(X_t)(t$ denotes a discrete time). A pair of orbits with period $p$ appears via saddle-node bifurcation, as the control parameter $A$ exceeds a threshold value $A_c$. One periodic orbit is a stable attractor, while the other one is an unstable repellor. However, as $A$ decreases below $A_c$, the two periodic orbits disappear, and an intermittent chaotic attractor, characterized by the occurrence of intermittent alternations between laminar and turbulent behaviors, appears.

One can easily explain the intermittency geometrically as follows. The curve of the equation $Y = u^p(X)[u^p]$ is the $p$th iterate of $u$] has new $2p$ intersection points with the $Y = X$ line for $A > A_c$, which collapse into $p$ points tangent to the $Y = X$ line for $A = A_c$ [i.e., we have $p$ fixed points, $X^p$...
Stability of a synchronous orbit of period \(p\) is determined from the Jacobian matrix \(J\) of \(M^{(p)}\) (\(p\)th iterate of \(M\)), which is given by the \(p\) product of the linearized map \(DM\) of the map (2.2) along the orbit

\[
J = \prod_{i=1}^{p} DM(X_t^*, X_t^*) = \prod_{i=1}^{p} \begin{pmatrix}
  u'(X_t^*) - V(X_t^*) & V(X_t^*) \\
  V(X_t^*) & u'(X_t^*) - V(X_t^*)
\end{pmatrix},
\]

(2.6)

where \(u'(x) = d u(x)/d x\) and \(V(x) = \partial u(x, y)/\partial y\vert_{y=x};\) hereafter \(V(x)\) will be referred to as the ‘‘reduced coupling function’’ of \(u(x, y)\). The eigenvalues of \(J\), called the stability multipliers of the orbit, are given by

\[
\lambda_1 = \prod_{i=1}^{p} u'(X_t^*), \quad \lambda_2 = \prod_{i=1}^{p} [u'(X_t^*) - 2V(X_t^*)].
\]

(2.7)

Note that \(\lambda_1\) is just the stability multiplier for the case of the uncoupled 1D map and the coupling affects only \(\lambda_2\).

A synchronous periodic orbit is stable when both multipliers lie inside the unit circle, i.e., \(|\lambda_j|<1\) for \(j=1\) and 2. Thus its stable region in the parameter plane is bounded by four bifurcation lines, i.e., those curves determined by the equations \(\lambda_j = \pm 1 (j=1, 2)\). When a multiplier \(\lambda_j\) increases through 1, the stable synchronous periodic orbit loses its stability via saddle-node or pitchfork bifurcation. On the other hand, when a multiplier \(\lambda_j\) decreases through 1, it becomes unstable via period-doubling bifurcation. (For more details on bifurcations, refer to Ref. [17].)

III. RENORMALIZATION ANALYSIS OF TWO-COUPLED MAPS

Here we are interested in intermittency just preceding a saddle-node bifurcation. Using the ‘‘reduced’’ renormalization method [10,11] developed for period doubling, we generalize the 1D results for intermittency to the case of two-coupled 1D maps. We thus find two fixed points of the reduced renormalization operator in Sec. III A and obtain their relevant eigenvalues in Sec. III B. We also study the intermittency for a dissipative-coupling case and confirm the renormalization results in Sec. III C.

A. Reduced renormalization operator and its fixed points

To study the intermittent transition to chaos near a saddle-node bifurcation to a pair of synchronous orbits of period \(p\), consider the \(p\)th iterate \(M^{(p)}\) of \(M\) of Eq. (2.2),

\[
M^{(p)}: X_{i+1} = W^{(p)}(X_i, Y_i), \quad Y_{i+1} = W^{(p)}(Y_i, X_i),
\]

(3.1)

where \(W^{(p)}\) satisfies a recurrence relation

\[
W^{(p)}(X, Y) = W(W^{(p-1)}(X, Y), W^{(p-1)}(Y, X)).
\]

(3.2)

The function \(W^{(p)}\) can be decomposed into the uncoupled part \(u^{(p)}\) and the remaining coupling part, i.e.,
\[ W^{(p)}(X,Y) = u^{(p)}(X) + [W^{(p)}(X,Y) - u^{(p)}(X)]. \]  

When the control parameter \( A \) of the uncoupled 1D map is equal to the threshold value \( A_c \) for the synchronous saddle-node bifurcation, we have \( p \) synchronous fixed points of \( M^{(p)} \) such that \( Y^* = X^* = u^{(p)}(X^*) \) for \( t = 1, \ldots, p \). Shifting the origin of coordinates \((X,Y)\) to one of the \( p \) synchronous fixed points \( (X^*,Y^*) \) \( [Y^* = X^* = u^{(p)}(X^*)] \) for \( A = A_c \), we have

\[
T:\begin{align*}
x_{t+1} &= F(x_t,y_t) - f(x_t) + g(x_t,y_t), \\
y_{t+1} &= F(y_t,x_t) - f(y_t) + g(y_t,x_t),
\end{align*}
\tag{3.4}
\]

where

\[
f(x) = u^{(p)}(x + X^*) - X^*,
\]

\[
g(x,y) = W^{(p)}(x + X^*, y + Y^*) - u^{(p)}(x + X^*).
\tag{3.6}
\]

Since a synchronous saddle-node bifurcation occurs at the origin \((0,0)\) for \( A = A_c \), in case of the map \( T \), the uncoupled part \( f \) for the critical case \( A = A_c \) satisfies

\[
f(0) = 0 \quad \text{and} \quad f'(0) = 1.
\tag{3.7}
\]

Note also that the coupling function \( g(x,y) \) satisfies the coupling condition (2.3), i.e.,

\[
g(x,x) = 0 \quad \text{for any} \quad x.
\tag{3.8}
\]

We employ the same renormalization transformation \([10,11]\) as in the period-doubling case with changed boundary conditions (3.7). The renormalization transformation \( \mathcal{N} \) for a coupled map \( T \) consists of squaring \( (T^2) \) and rescaling \( (B) \) operators:

\[ \mathcal{N}(T) = B T^2 B^{-1}. \tag{3.9} \]

Since we consider only synchronous orbits, the rescaling operator is of the form

\[ B = \begin{pmatrix} \alpha & 0 \\ 0 & \alpha \end{pmatrix}, \tag{3.10} \]

where \( \alpha \) is a rescaling factor.

Applying the renormalization operator \( \mathcal{N} \) to the coupled map (3.4) \( n \) times, we obtain the \( n \)-times renormalized map \( T_n \) of the form

\[ T_n:\begin{align*}
x_{t+1} &= F_n(x_t,y_t) - f_n(x_t) + g_n(x_t,y_t), \\
y_{t+1} &= F_n(y_t,x_t) - f_n(y_t) + g_n(y_t,x_t).
\end{align*}
\tag{3.11}
\]

Here \( f_n \) and \( g_n \) are the uncoupled and coupling parts of the \( n \)-times renormalized function \( F_n \), respectively. They satisfy the following recurrence equations \([10,11]\):

\[ f_{n+1}(x) = \alpha f_n \left( f_n \left( \frac{x}{\alpha} \right) \right), \tag{3.12} \]

\[ g_{n+1}(x,y) = \alpha f_n \left( f_n \left( \frac{x}{\alpha} \right) + g_n \left( \frac{x}{\alpha} \right) \right) \\
+ \alpha g_n \left( f_n \left( \frac{y}{\alpha} \right) + g_n \left( \frac{y}{\alpha} \right) \right) + g_n \left( \frac{y}{\alpha} \right)
\tag{3.13} \]

Then Eqs. (3.12) and (3.13) define a renormalization operator \( \mathcal{R} \) of transforming a pair of functions, \((f,g)\):

\[ \begin{pmatrix} f_{n+1} \\ g_{n+1} \end{pmatrix} = \mathcal{R} \begin{pmatrix} f_n \\ g_n \end{pmatrix}. \tag{3.14} \]

A critical map \( T_c \) with the nonlinearity and coupling parameters set to their critical values is attracted to a fixed map \( T^* \) under iterations of the renormalization transformation \( \mathcal{N} \):

\[ T^*:\begin{align*}
x_{t+1} &= F^*(x_t,y_t) - f^*(x_t) + g^*(x_t,y_t), \\
y_{t+1} &= F^*(y_t,x_t) - f^*(y_t) + g^*(y_t,x_t).
\end{align*}
\tag{3.15} \]

Here \((f^*,g^*)\) is a fixed point of the renormalization operator \( \mathcal{R} \), which satisfies \((f^*,g^*) = \mathcal{R}(f^*,g^*)\). Note that the equation for \( f^* \) is just the fixed-point equation for the intermittency with boundary conditions (3.7) in the uncoupled 1D map. It has been found in \([3]\) that

\[ f^*(x) = x[1 - (z - 1)a x^{z-1}]^{-1/(z-1)} \\
= x + a x^z + \frac{z}{2} a^2 x^{2z-1} + \ldots
\]

\[ (a:\text{arbitrary constant}) \tag{3.16} \]

is a fixed point of the transformation (3.12) with

\[ \alpha = 2^{1/(z-1)}. \tag{3.17} \]

[As mentioned in Sec. II, we consider only the analytic case of even order \( z(= 2,4,6,\ldots.) \). Consequently, only the equation for the coupling fixed function \( g^* \) is left to be solved.

However, it is not easy to directly solve the equation for the coupling fixed function. We therefore introduce a tractable recurrence equation for a reduced coupling function of the coupling function \( g(x,y) \), defined by

\[ G(x) = \frac{\partial g(x,y)}{\partial y} \bigg|_{y=x}. \tag{3.18} \]

Differentiating the recurrence equation (3.13) for \( g \) with respect to \( y \) and setting \( y = x \), we have

\[ G_{n+1}(x) = \left[ f_n' \left( f_n \left( \frac{x}{\alpha} \right) \right) - 2 G_n \left( f_n \left( \frac{x}{\alpha} \right) \right) G_n \left( \frac{x}{\alpha} \right) \right] + G_n \left( f_n \left( \frac{x}{\alpha} \right) \right) \tag{3.19} \]

Then Eqs. (3.12) and (3.19) define a “reduced renormalization operator” \( \mathcal{R} \) of transforming a pair of functions \((f,G)\) \([10,11]\):
corresponding to the two fixed points of the reduced renormalization operator, \(G^*\). Note that \(G^*\) is just the reduced coupling fixed function of \(g^*\) [i.e., \(G^*(x) = \partial g^*(x,y)/\partial y|_{y=x}\)]. Using a series-expansion method, we find two solutions for \(G^*\):

\[
G_1^*(x) = \frac{1}{2} \left[ 1 + za x^{z-1} + z - \frac{1}{2} a^2 x^{2(z-1)} + \ldots \right],
\]

\(3.21\)

\[
G_2^*(x) = \frac{1}{2} \left[ ba x^{z-1} + b \left( \frac{3z-b}{2} - \frac{1}{2} \right) a^2 x^{2(z-1)} + \ldots \right],
\]

\(3.22\)

where \(a\) and \(b\) are arbitrary constants. Here we are able to sum the series in Eq. (3.21) and obtain a closed-form solution,

\[
G_1^*(x) = \frac{1}{2} f^*(x).
\]

\(3.23\)

However, unfortunately we cannot sum the series in Eq. (3.22), except for the cases \(b = 0\) and \(z\) where we obtain closed-form solutions,

\[
G_2^*(x) = \left\{ \begin{array}{ll}
0, & \text{for } b = 0 \\
\frac{1}{2} [f^*(x)-1], & \text{for } b = z.
\end{array} \right.
\]

\(3.24\)

We have also studied the intermittency using another renormalization method including a truncation [15]. Two fixed points of the approximate renormalization operator, corresponding to the two fixed points of the reduced renormalization operator \(\tilde{R}\), have been found. The relevant eigenvalues of the truncated fixed points are also the same as those of the two fixed points of \(\tilde{R}\), which will be obtained below.

B. Reduced linearized operator and its relevant eigenvalues

Once a fixed point \((f^*, g^*)\) of the renormalization operator \(\mathcal{R}\) is determined, its eigenvalues are obtained by linearizing \(\mathcal{R}\) at the fixed point and solving the resultant eigenvalue problem. In general, it is required to know the coupling fixed function \(g^*(x,y)\) to linearize \(\mathcal{R}\) around a fixed point \((f^*, g^*)\). However, it is shown that the eigenvalues are possibly obtained using the reduced coupling fixed function \(G^*(x)\) rather than \(g^*(x,y)\). We thus obtain the relevant eigenvalues of the two fixed points as follows.

Let us examine the evolution of a pair of functions, \([f^*(x), h(x), g^*(x,y), \phi(x,y)]\), close to a fixed point \((f^*, g^*)\) under \(\mathcal{R}\). Linearizing the renormalization operator \(\mathcal{R}\) at the fixed point \((f^*, g^*)\), we obtain the recurrence equation for the evolution of a pair of infinitesimal perturbations \((h, \phi)\):

\[
\begin{pmatrix} h_{n+1} \\ \varphi_{n+1} \end{pmatrix} = \mathcal{L} \begin{pmatrix} h_n \\ \varphi_n \end{pmatrix} = \begin{pmatrix} \mathcal{L}_1 & 0 \\ \mathcal{L}_3 & \mathcal{L}_2 \end{pmatrix} \begin{pmatrix} h_n \\ \varphi_n \end{pmatrix},
\]

\(3.25\)

where

\[
h_{n+1}(x) = [\mathcal{L}_1 h_n](x),
\]

\(3.26\)

\[
\varphi_{n+1}(x) = [\mathcal{L}_2 \varphi_n](x,y) + [\mathcal{L}_3 h_n](x),
\]

\(3.27\)

\[
[\mathcal{L}_2 \varphi_n](x,y) = \alpha F_1 \left( \frac{y}{\alpha} \right) \varphi_n \left( \frac{y}{\alpha} \right) + \alpha F_2 \left( \frac{y}{\alpha} \right) \left[ \varphi_n \left( \frac{y}{\alpha} \right) - \varphi_n \left( \frac{y}{\alpha} \right) \right],
\]

\(3.28\)

\[
[\mathcal{L}_3 h_n](x) = \alpha F_1 \left( \frac{y}{\alpha} \right) \varphi_n \left( \frac{y}{\alpha} \right) + \alpha F_2 \left( \frac{y}{\alpha} \right) \left[ \varphi_n \left( \frac{y}{\alpha} \right) - \varphi_n \left( \frac{y}{\alpha} \right) \right] + \alpha h_n \left[ \varphi_n \left( \frac{y}{\alpha} \right) - \varphi_n \left( \frac{y}{\alpha} \right) \right] - [\mathcal{L}_1 h_n](x).
\]

\(3.29\)

Here \(F^*(x,y) = f^*(x) + g^*(x,y)\), and the subscript \(i\) \((i = 1, 2)\) of \(F^*\) denotes the partial derivative with respect to the \(i\)th argument. Note that, although \(h_n\) couples to both \(h_{n+1}\) and \(\varphi_{n+1}\), \(\varphi_n\) couples only to \(\varphi_{n+1}\). From this reducibility of \(\mathcal{L}\) into a semiblock form, it follows that to obtain the eigenvalues of \(\mathcal{L}\) it is sufficient to solve the eigenvalue problems for \(\mathcal{L}_1\) and \(\mathcal{L}_2\) separately. The eigenvalues of both \(\mathcal{L}_1\) and \(\mathcal{L}_2\) give the whole spectrum of \(\mathcal{L}\).

A pair of perturbations \((h^*, \varphi^*)\) is called an eigenperturbation with eigenvalue \(\lambda\), if

\[
\mathcal{L} \begin{pmatrix} h^* \\ \varphi^* \end{pmatrix} = \lambda \begin{pmatrix} h^* \\ \varphi^* \end{pmatrix},
\]

\(3.30\)

that is,

\[
\lambda h^*(x) = [\mathcal{L}_1 h^*](x),
\]

\(3.31\)

\[
\lambda \varphi^*(x,y) = [\mathcal{L}_2 \varphi^*](x,y) + [\mathcal{L}_3 h^*](x).\]

\(3.32\)

We first solve Eq. (3.31) to find eigenvalues of \(\mathcal{L}_1\). Note that this is just the eigenvalue equation in the 1D map case. The complete spectrum of eigenvalues and the corresponding eigenfunctions have been found in Refs. [3]. The form of the eigenvalues is \(\lambda_n = 2^{(z-n)/(z-1)} (n = 0, 1, 2, \ldots)\). Hence the first \(z\) eigenvalues with \(n < z\) are relevant ones. The marginal one \(\lambda_z\) is associated with the arbitrary constant \(a\) in \(f^*(x)\), and all the other ones with \(n > z\) are irrelevant. Although the eigenvalues \(\lambda_n\)’s of \(\mathcal{L}_1\) are also eigenvalues of \(\mathcal{L}\) as mentioned in the preceding paragraph, \((h^*,0)\) itself cannot be an eigenperturbation of \(\mathcal{L}\) unless \(\mathcal{L}_3\) is a null operator.

Next, we consider a perturbation of the form \((0, \varphi)\) having only the coupling part. In this case \((0, \varphi^*)\) is an eigenperturbation of \(\mathcal{L}\) with eigenvalue \(\lambda\), only if \(\varphi^*\) satisfies
\[ \lambda \varphi^*(x,y) = \mathcal{L}_2 \varphi^*(x,y). \]  

(3.33)

The eigenvalues associated with the coupling perturbations will be called the coupling eigenvalues (CE’s).

However, it is not easy to directly solve the eigenvalue equation for \( \varphi^* \). We therefore introduce a tractable recurrence equation for a reduced coupling perturbation of the coupling perturbation \( \varphi(x,y) \), defined by \( \Phi(x) = \varphi(x,y)/(\partial y)_{y=x} \). In the case of general perturbations \( (h, \varphi) \), differentiating the recurrence equation (3.27) with respect to \( y \) and setting \( y = x \), we obtain a recurrence equation for \( \Phi \):

\[ \Phi_{n+1}(x) = \left[ \tilde{\mathcal{L}}_2 \Phi_n(x) \right] + \left[ \tilde{\mathcal{L}}_3 h_n(x) \right], \]

(3.34)

\[ \left[ \tilde{\mathcal{L}}_2 \Phi_n(x) \right] = \left[ f^* \left( f^* \left( \frac{x}{\alpha} \right) \right) G^* \left( \frac{x}{\alpha} \right) - 2 G^* \left( \frac{x}{\alpha} \right) f^* \left( \frac{x}{\alpha} \right) G^* \left( \frac{x}{\alpha} \right) \right] \Phi^* \left( \frac{x}{\alpha} \right) \]

\[ + \left[ f^* \left( \frac{x}{\alpha} \right) G^* \left( \frac{x}{\alpha} \right) h_n \left( \frac{x}{\alpha} \right) + G^* \left( \frac{x}{\alpha} \right) h_n \left( \frac{x}{\alpha} \right) f^* \left( \frac{x}{\alpha} \right) \right] \Phi^* \left( \frac{x}{\alpha} \right). \]

(3.35)

Then the recurrence equations (3.26) and (3.34) for \( h \) and \( \Phi \) define a reduced linearized operator \( \tilde{\mathcal{L}} \) of transforming a pair of perturbations, \( (h, \Phi) \):

\[ \begin{pmatrix} h_{n+1} \\ \Phi_{n+1} \end{pmatrix} = \tilde{\mathcal{L}} \begin{pmatrix} h_n \\ \Phi_n \end{pmatrix} = \begin{pmatrix} \mathcal{L}_1 & 0 \\ \mathcal{L}_3 & \mathcal{L}_2 \end{pmatrix} \begin{pmatrix} h_n \\ \Phi_n \end{pmatrix}. \]

(3.37)

Note that this equation can also be obtained by directly linearizing the reduced renormalization operator \( \tilde{\mathcal{R}} \) of Eq. (3.20) at its fixed point \( (f^*, G^*) \). Hence, Eq. (3.37) is just the eigenvalue equation for the fixed point \( (f^*, G^*) \) of \( \tilde{\mathcal{R}} \).

The reducibility of \( \tilde{\mathcal{L}} \) into a semiblock form again lets us search for the reduced coupling eigenperturbations of the form \( (0, \Phi^*) \), where \( \Phi^*(x) \) satisfies

\[ \lambda \Phi^*(x) = \left[ \tilde{\mathcal{L}}_2 \Phi \right]^{*}(x) \]

\[ = \left[ f^* \left( f^* \left( \frac{x}{\alpha} \right) \right) - 2 G^* \left( \frac{x}{\alpha} \right) f^* \left( \frac{x}{\alpha} \right) G^* \left( \frac{x}{\alpha} \right) \right] \Phi^* \left( \frac{x}{\alpha} \right) \]

\[ + \left[ f^* \left( \frac{x}{\alpha} \right) G^* \left( \frac{x}{\alpha} \right) h \left( \frac{x}{\alpha} \right) + G^* \left( \frac{x}{\alpha} \right) h \left( \frac{x}{\alpha} \right) f^* \left( \frac{x}{\alpha} \right) \right] \Phi^* \left( \frac{x}{\alpha} \right). \]

(3.38)

Here the prime denotes a derivative with respect to \( x \). Note that this equation for \( \Phi^* \) is just a reduced equation of the original eigenvalue equation (3.33) for \( \varphi^* \), obtained by differentiating Eq. (3.33) with respect to \( y \) and setting \( y = x \). Clearly all eigenvalues \( \lambda \) of this reduced eigenvalue equation are also eigenvalues of the original eigenvalue equation (3.33). That is, each eigenfunction \( \Phi^*(x) \) with a CE \( \lambda \) corresponds to the reduced coupling eigenfunction of the original coupling eigenfunction \( \varphi^*(x,y) \) with the same CE \( \lambda \).

To solve the reduced eigenvalue equation (3.38), it is sufficient to know only the reduced coupling fixed function \( G^*(x) \) of \( g^*(x,y) \). Using the two solutions for \( G^* \) in Eqs. (3.21) and (3.22), we obtain the relevant CE’s, which vary depending on \( G^*(x) \), as follows. We first consider the case of the first solution \( G_{11}^*(x) = \frac{1}{2} f^*(x) \). In this case the reduced linearized operator \( \tilde{\mathcal{L}}_2 \) of Eq. (3.38) becomes a null operator, because the right-hand side of the equation becomes zero. Hence there exist no relevant CE’s associated with coupling perturbations, and consequently the fixed point \( (f^*, G_{11}^*) \) of \( \tilde{\mathcal{R}} \) has only relevant eigenvalues of \( \mathcal{L}_1 \), associated with the scaling of the control parameter of the uncoupled 1D map, like the 1D case.

Second, consider the case of the second solution \( G_{12}^* \) of Eq. (3.22). Using a series-expansion method, we find the complete spectrum of CE’s and the corresponding eigenfunctions. An eigenfunction \( \Phi^*(x) \) can be expanded as follows:

\[ \Phi^*(x) = \sum_{l=0}^{\infty} c_l x^l. \]

(3.39)

Substituting the power series of \( f^*(x) \), \( f^* \left( \frac{x}{\alpha} \right) \), \( G_{12}^*(x) \), and \( \Phi^*(x) \) into the reduced eigenvalue equation (3.38), it has the structure

\[ \lambda c_k = \sum_{l}^{\infty} M_{kl} c_l, \quad k,l = 0,1,2,\ldots. \]

(3.40)

Note that each \( c_l \) with \( l = 0,1,2,\ldots \) in the right-hand side is involved only in the determination of coefficients of monomials \( x^{l+k} \) with \( k = l + m(z-1) \) \((m = 0,1,2,\ldots)\). Hence \( M \) becomes a lower triangular matrix. Its eigenvalues are therefore just diagonal elements:

\[ \lambda_k = M_{kk} = \frac{2}{\alpha^k} = 2^{(z-1-k)(z-1)}, \quad k = 0,1,2,\ldots. \]

(3.41)

The first \( (z-1) \) eigenvalues \( \lambda_k \)’s for \( 0 \leq k \leq z-2 \) are relevant ones. The marginal eigenvalue \( \lambda_{z-1} \) is associated with
the arbitrary constant \( b \) in \( G^s_{\theta_0}(x) \), and all the other eigenvalues for \( k > z - 1 \) are irrelevant.

Each eigenfunction \( \Phi^s_k(x) \) with CE \( \lambda_k(k=0,1,2,\ldots) \) is of the form

\[
\Phi^s_k(x) = x^k \left[ 1 + \frac{z - b + \frac{k}{2} a x^{z-1} + \cdots \right].
\]  

(3.42)

In case of the largest CE \( \lambda_0=2 \), we are able to sum the series in Eq. (3.42) for \( b=0 \) and \( z \) and find \( \Phi^s_0(x) \) in closed form:

\[
\Phi^s_0(x) = \begin{cases} 
  f^{s*}(x), & \text{for } b=0, \\
  1, & \text{for } b=z.
\end{cases}
\]  

(3.43)

We can also sum the series in Eq. (3.42) for all the irrelevant cases (i.e., the cases \( k \geq z \)) and find the closed-form eigenfunctions,

\[
\Phi^s_k(x) = \frac{1}{a^l} [f^{s*}(x) - 2G^s_{\theta_0}(x)] [f^{s*}(x) - x^l],
\]  

(3.44)

where the uncoupled and coupling parts \( f \) and \( g \) are given by

\[
f(x) = u^{(3)}(x + X^s*) - X^s*,
\]  

(3.47)

\[
g(x,y) = W^{(3)}(x + X^*,y + Y^*) - u^{(3)}(x + X^*).
\]  

(3.48)

Near the region of the synchronous saddle-node bifurcation, \( f(x) \) can be expanded about \( x=0 \) and \( A=\Lambda_c \),

\[
f(x) \approx x + a x^2 + \epsilon,
\]  

(3.49)

where

\[
a = \frac{1}{2} \frac{\partial^2 f}{\partial x^2} |_{x=0,A=\Lambda_c}, \quad \epsilon = \frac{\partial f}{\partial A} |_{x=0,A=\Lambda_c}(A - \Lambda_c).
\]

Hence this corresponds to the most common case with the tangency order \( z=2 \) [see Eq. (2.1)]. Note also that the reduced coupling function \( G(x) \) of \( g(x,y) \) [defined in Eq. (3.18)] is also given by

\[
G(x) = \frac{e}{2} f'(x), \quad e = \epsilon - 3 \epsilon^2 + 3c.
\]  

(3.50)

Consider a pair of initial functions \((f_c,G)\) on the synchronous saddle-node bifurcation line \( \Lambda = \Lambda_c \), where \( f_c(x) \) is just the 1D critical map and \( G(x) = (\epsilon/2)f_c(x) \). By successive actions of the reduced renormalization transformation \( \overline{R} \) of Eq. (3.20) on \((f_c,G)\), we obtain

\[
f_n(x) = \alpha f_{n-1} \left( \frac{x}{\alpha} \right), \quad G_n(x) = \frac{e_n}{2} f'_n(x),
\]  

(3.51)

\[
e_n = 2e_{n-1} - e_{n-1}^2, \quad (n=0,1,2,\ldots),
\]  

(3.52)

where the rescaling factor for \( z=2 \) is \( \alpha = 2 \), \( f_0(x) = f_c(x) \), \( G_0(x) = G(x) \), and \( e_0 = \epsilon \). Here \( f_n \) converges to the 1D fixed function \( f^{s*}(x) \) of Eq. (3.16) with \( z=2 \) as \( n \to \infty \).

We now investigate the evolution of \( G(x) \) under iterations of \( \overline{R} \). Figure 1 shows a plot of the curve determined by Eq. (3.52). Two intersection points between this curve and the straight line \( e_n = e_{n-1} \) are just the fixed points \( e^{s*} \) of the recurrence relation (3.52) for \( e \)

\[
e^{s*} = 0.1.
\]  

(3.53)

Stability of each fixed point \( e^{s*} \) is determined by its stability multiplier \( \mu \). The fixed point at \( e^{s*} = 1 \) is superstable \( \mu = 0 \), while the other one at \( e^{s*} = 0 \) is unstable \( \mu = 2 \). The basin of attraction to the superstable fixed point \( e^{s*} = 1 \) is the open interval \((0,2)\). That is, any initial \( e \) inside the interval \( 0 < e < 2 \) converges to \( e^{s*} = 1 \) under successive iterations of the transformation (3.52). The left end of the interval is just the unstable fixed point \( e^{s*} = 0 \), which is also the image of the right end point under the recurrence equation (3.52). All the other points outside the interval diverge.

C. Critical behaviors near a critical line

In order to confirm the above renormalization results, we study the intermittency in the dissipatively coupled 1D maps. It is found that there exists a critical line segment associated with intermittency in the parameter plane. We explicitly show that any pair of critical functions \((f_c,G_c)\) at any interior point of the critical line is attracted to the first fixed point \((f^{s*},G^{s*})\) under iterations of the reduced renormalization operator \( \overline{R} \), while the pair of critical functions \((f_c,G_c)\) at each end point converges to the second fixed point \((f^{s*},G^{s*})\) of \( \overline{R} \). Consequently, the critical behaviors inside the critical line are governed by the first fixed point \((f^{s*},G^{s*})\) with no relevant CE’s. On the other hand, the second fixed point with relevant CE’s governs the critical behaviors at both ends of the critical line. The first fixed point with no CE’s has the same relevant eigenvalues as the 1D fixed point. Therefore, the critical behaviors inside the critical line become the same as those for the 1D case. However, such a 1D-like intermittent transition to chaos, occurring on the synchronization line, ends at both ends of the critical line because of the system desynchronization. The scaling behaviors of the coupling parameter near both ends are governed by the relevant CE of the second fixed point. Note also that this kind of critical behaviors near a critical line are also found for a linear-coupling case [15].

We now choose the uncoupled 1D map in two-coupled 1D maps \( M \) of Eq. (2.2) as

\[
u(X,Y) = \frac{c}{2} [u(Y) - u(X)].
\]  

(3.46)
to the minus infinity under iterations of the transformation (3.52). Thus there exists a critical line segment joining two end points \( c_1 = 0 \) (corresponding to \( e = 0 \)) and \( c_r = 2 \) (corresponding to \( e = 2 \)) on the synchronous saddle-node bifurcation line \( A = A_c \) in the \( c - A \) plane.

Any initial \( G(x) \) inside the critical line is attracted to the first reduced coupling fixed function \( G^*_1(x) = \frac{1}{2} f^*(x) \) under iterations of \( \tilde{R} \), which corresponds to the fixed point \( e^* = 1 \). Consequently, the critical behaviors inside the critical line are governed by the first fixed point \( (f^*, G^*_1) \) of \( \tilde{R} \). This first fixed point has no relevant CE’s, because the fixed point \( e^* = 1 \) of the transformation (3.52) is superstable. Hence it has only the relevant eigenvalues of \( L_1 \) (i.e., those of the 1D fixed point).

Since the tangency order for the dissipatively coupled case is \( \varepsilon = 2 \), there exist two relevant eigenvalues of \( L_1 \), \( \delta_1 = 4 \), and \( \delta_1^* = 2 \). On the other hand, \( G(x) \)’s at both ends of the critical line converge to the second reduced coupling fixed function \( G^*_2(x) = 0 \) with \( b = 0 \), which corresponds to the fixed point \( e^* = 0 \). Accordingly, the second fixed point \( (f^*, G^*_2) \) governs the critical behaviors at both ends. In addition to the common relevant eigenvalues \( \delta_1 \) and \( \delta_1^* \), this second fixed point has one relevant CE \( \delta_2 = 2 \), because the fixed point \( e^* = 0 \) of the transformation (3.52) is an unstable one with stability multiplier \( \mu = 2 \).

From now on, we present the detailed results on the critical behaviors near the critical line, governed by the two fixed points of \( \tilde{R} \). Figure 2 shows a phase diagram near the critical line denoted by a solid line. The diagram is obtained from calculation of Lyapunov exponents. For the case of a synchronous orbit, its two Lyapunov exponents are given by

\[
\sigma_1(A) = \lim_{m \to \infty} \frac{1}{m} \sum_{i=0}^{m-1} \ln|u'(X_i)|, \quad (3.54)
\]

\[
\sigma_{\perp}(A,c) = \lim_{m \to \infty} \frac{1}{m} \sum_{i=0}^{m-1} \ln|(1-c)u'(X_i)| = \sigma_1(A) + \ln|1 - c|, \quad (3.55)
\]
with exponent

The scaling relations of the mean duration of the laminar phase $T$ and the tangential Lyapunov exponent $\sigma_l$ for a synchronous chaotic attractor are obtained from the leading relevant eigenvalue $\delta_l$ (4) of the first fixed point $(f^*,G^*_l)$, like the 1D case [3]. A map with nonzero $e$ near an interior point of the critical line segment is transformed into a new map of the same form, but with a new parameter $e'$ under a renormalization transformation. Here the control parameter scales as

$$e'_A = \delta_1 e_A = 2^2 e_A. \tag{3.56}$$

Then the mean duration $T$ and the tangential Lyapunov exponent $\sigma_l$ satisfy the homogeneity relations,

$$T(e'_A) = \frac{1}{2} T(e_A), \quad \sigma_l(e'_A) = 2 \sigma_l(e_A), \tag{3.57}$$

which lead to the scaling relations,

$$T(e_A) \sim e_A^{-\mu}, \quad \sigma_l(e_A) \sim e_A^\mu, \tag{3.58}$$

with exponent

$$\mu = \ln 2/\ln \delta_1 = 0.5. \tag{3.59}$$

The above 1D-like intermittent transition to chaos ends at both ends $c_l$ and $c_r$ of the critical line segment. We fix the control parameter $A$ at the synchronous saddle-node bifurcation value $A_c = 1.75$ and study the critical behaviors near the two end points, governed by the second fixed point $(f^*,G^*_l)$, by varying the coupling parameter $c$. Inside the critical line segment ($c_l < c < c_r$), a synchronous period-3 attractor with $\sigma_2 < 0$ exists on the synchronization line, and hence the coupling tends to synchronize the interacting systems. However, as the coupling parameter $c$ passes through $c_l$ or $c_r$, the transversal Lyapunov exponent $\sigma_\perp$ of the synchronous periodic orbit increases from zero, as shown in Fig. 3, and hence the coupling leads to desynchronization of the interacting systems. Thus the synchronous period-3 orbit ceases to be an attractor outside the critical line segment, and a new (out-of-phase) asynchronous attractor appears. This is illustrated in Fig. 4. As a result of this transition from a synchronous to an asynchronous state for $A = A_c$, the 1D-like intermittent transition to chaos, occurring on the synchronization line, ends when crossing both ends of the critical line.

The critical behaviors near both ends $c_l$ and $c_r$ are the same. Since the transversal Lyapunov exponent $\sigma_\perp$ is equal to $\ln|1-c|$ for $A = A_c$ [see Eq. (3.55)], it varies linearly with respect to $c$ near both ends (i.e., $\sigma_\perp \sim c$, $c = c_l$ or $c = c_r$). The scaling behavior of $\sigma_\perp$ is obtained from the relevant CE $\delta_2$ (=2) of the second fixed point $(f^*,G^*_l)$ as follows. Consider a map with nonzero $e_c$, (but with $e_A = 0$) near both ends. It is then transformed into a new one of the same form, but with a renormalized parameter $e'_c$ under a renormalization transformation. Here the parameter $e_c$ obeys a scaling law,

$$e'_c = \delta_2 e_c = 2 e_c. \tag{3.60}$$

Then the transversal Lyapunov exponent $\sigma_\perp$ satisfies the homogeneity relation,

$$\sigma_\perp(e'_c) = 2 \sigma_\perp(e_c). \tag{3.61}$$

This leads to the scaling relation,

$$\sigma_\perp(e_c) \sim e'_c, \tag{3.62}$$

with exponent

\[ \text{FIG. 4. Plot of } \sigma_\perp(=\ln|1-c|) \text{ versus } c \text{ for } A=A_c. \text{ The values of } \sigma_\perp \text{ at both ends of the critical line segment are zero, which are denoted by solid circles.} \]
INTERMITTENCY IN COUPLED MAPS

Recently, much attention has been paid to dynamical systems with many nonlinear elements and a global coupling, in which each element is coupled to all the other elements with equal strength. Globally coupled systems as the extreme limit of long-range couplings are seen in broad branches of science [16]. For example, coupled nonlinear oscillators with a global coupling frequently occur in charge density waves [19]. Josephson junction arrays [20], and p-n junction arrays [21]. This kind of dynamical systems with a global coupling can be also regarded as mean-field versions of dynamical systems with local short-range couplings. Here we first introduce many globally coupled 1D maps in Sec. IV A, and then show that the critical behaviors of $N$ globally coupled maps for $N>2$ are the same as those of the two dissipatively coupled maps in Sec. IV B. In the final section IV C, the renormalization results of the two coupled maps are straightforwardly extended to the many globally coupled maps.

A. Many globally coupled 1D maps

Consider an $N$-coupled map with a periodic boundary condition:

$$
M: X_{t+1}(m) = W(a^{m-1}X_{t})
$$

$$
= W(X_{t}(m), X_{t}(m+1), \ldots, X_{t}(m-1)),
$$

$$
m = 1, \ldots, N,
$$

(4.1)

where the number of constituent elements $N$ is a positive integer larger than or equal to 2. $X_{t}(m)$ is the state of the $m$th element at a lattice point $m$ and at a discrete time $t$. $X = (X(1), X(2), \ldots, X(N))$, $\sigma$ is the cyclic permutation of the elements of $X$, i.e., $\sigma X = (X(2), \ldots, X(N), X(1))$, $\sigma^{m-1}$ means $(m-1)$ applications of $\sigma$. The periodic condition imposes $X_{t}(m) = X_{t}(m+N)$ for all $m$. Like the two-coupled case ($N=2$), the function $W$ consists of two parts:

$$
W(X) = u(X(1)) + v(X),
$$

(4.2)

where $u$ is an uncoupled 1D map and $v$ is a coupling function obeying the condition

$$
v(X, \ldots, X) = 0, \text{ for any } X.
$$

(4.3)

Thus the $N$-coupled map (4.1) becomes

$$
M: X_{t+1}(m) = u(X_{t}(m)) + v(X_{t}(m), X_{t}(m+1), \ldots, X_{t}(m-1)),
$$

$$
m = 1, \ldots, N.
$$

(4.4)

Here we study many-coupled 1D maps with a global coupling. In the extreme long-range case of global coupling, the coupling function $v$ is of the form

$$
v(X(1), \ldots, X(N)) = \frac{c}{N} \sum_{n=1}^{N} [r(X(n)) - r(X(1))] \text{ for } N \geq 2,
$$

(4.5)

where $r(X)$ is a function of one variable. Note that each 1D map is coupled to all the other ones with equal coupling strength $c/N$ inversely proportional to the number of degrees of freedom $N$. Hereafter, $c$ will be called the coupling parameter.

The $N$-coupled map $M$ is called a symmetric map, because it has a cyclic permutation symmetry such that
where $\sigma^{-1}$ is the inverse of $\sigma$. The set of all fixed points of $\sigma$ forms a synchronization line in the $N$-dimensional state space, on which

$$X(1) = \cdots = X(N).$$

(4.7)

It follows from Eq. (4.6) that the cyclic permutation $\sigma$ commutes with the symmetric map $M$, i.e., $\sigma M = M \sigma$. Hence the synchronization line becomes invariant under $M$. An orbit is called a(n) (in-phase) synchronous orbit if it lies on the synchronization line, i.e., it satisfies

$$X_i(1) = \cdots = X_i(N) = X_i^e,$$  \hspace{0.5cm} \text{for all } i. \hspace{0.5cm} (4.8)

Otherwise, it is called an (out-of-phase) asynchronous orbit. Here we study the intermittency associated with a synchronous saddle-node bifurcation. Note also that synchronous or\-th-mode perturbations can be easily found from the uncoupled 1D map, $X_t = u(X_t^e)$, because of the coupling condition (4.3).

**B. Critical behaviors for the globally coupled case**

Here we first discuss Lyapunov exponents of the synchron-\-ous orbits of $N$ globally coupled maps, and show that there exists only one independent transversal Lyapunov exponent, independently of $N$, which is also the same as that for the case of two dissipatively coupled maps. It follows from this fact that the critical behaviors of $N$ globally coupled maps for $N \geq 2$ becomes the same as those of the two dissipatively coupled maps.

Consider an orbit $\{X_t\} = \{X_t(m), m = 1, \ldots, N\}$ in many coupled maps (4.4). Stability analysis of the orbit can be easily carried out by Fourier transforming with respect to the discrete space $\{m\}$. The discrete spatial Fourier transform of the orbit is

$$\mathcal{F}[X_t(m)] = \frac{1}{N} \sum_{m=1}^{N} e^{-2\pi imj/N} X_t(m) = \xi_j(j),$$

$$j = 0, 1, \ldots, N - 1. \hspace{0.5cm} (4.9)$$

The Fourier transform $\xi_j(j)$ satisfies $\xi_j^*(j) = \xi_j(N-j)$ (* denotes complex conjugate), and the wavelength of a mode with index $j$ is $N/j$ for $j \leq N/2$ and $N/(N-j)$ for $j > N/2$. Here $\xi_j(0)$ corresponds to the synchronous (Fourier) mode of the orbit, while all the other $\xi_j(j)$’s with nonzero indices $j$ correspond to the asynchronous (Fourier) modes.

To determine the stability of a synchronous orbit $\{X_t(1) = \cdots = X_t(N) = X_t^e\}$ for all $t$, we consider an infinitesimal perturbation $\{\Delta X_t(m)\}$ to the synchronous orbit, i.e., $X_t(m) = X_t^e + \Delta X_t(m)$ for $m = 1, \ldots, N$. Linearizing the $N$-coupled map (4.4) at the synchronous orbit, we obtain

$$\Delta X_{m+1}(m) = u'(X_t^e)\Delta X_t(m) + \sum_{i=1}^{N} V^{(i)}(X_t^e)\Delta X_t(l+m-1),$$

$$\hspace{0.5cm} (4.10)$$

where

$$u'(X) = \frac{du}{dx}, \hspace{0.5cm} V^{(i)}(X) = \frac{\partial v(\sigma^{i-1}X)}{\partial X_i} \mid_{X(1) = \cdots = X(N) = X}$$

$$= \frac{\partial v(X)}{\partial X_i} \mid_{X(1) = \cdots = X(N) = X}. \hspace{0.5cm} (4.11)$$

Hereafter, the functions $V^{(i)}$’s will be called “reduced coupling functions” of $v(X)$.

Let $\delta \xi_j(j)$ be the Fourier transform of $\Delta X_t(m)$, i.e.,

$$\delta \xi_j(j) = \mathcal{F}[\Delta X_t(m)] = \frac{1}{N} \sum_{m=1}^{N} e^{-2\pi imj/N} \Delta X_t(m),$$

$$j = 0, 1, \ldots, N - 1. \hspace{0.5cm} (4.12)$$

Here $\delta \xi_j(0)$ is the synchronous-mode perturbation along the synchronization line, while all the other ones $\delta \xi_j(j)$’s with nonzero indices $j$ are the asynchronous-mode perturbations across the synchronization line. Then the Fourier transform of Eq. (4.10) becomes

$$\delta \xi_{j+1}(j) = \left[u'(X_t^e) + \sum_{i=1}^{N} V^{(i)}(X_t^e) e^{2\pi i(l-1)/N}\right] \delta \xi_j(j),$$

$$j = 0, 1, \ldots, N - 1. \hspace{0.5cm} (4.13)$$

Note that all the modes $\xi_j(j)$’s become decoupled for the synchronous orbit.

The Lyapunov exponent $\lambda_j$ of a synchronous orbit, characterizing the average exponential rate of divergence of the $j$th-mode perturbation, is given by

$$\sigma_j = \lim_{m \to \infty} \frac{1}{m} \sum_{i=0}^{m-1} \ln \left|u'(X_t^e) + \sum_{i=1}^{N} V^{(i)}(X_t^e) e^{2\pi i(l-1)/N}\right|. \hspace{0.5cm} (4.14)$$

If the Lyapunov exponent $\sigma_j$ is negative or zero, then the synchronous orbit is stable against the $j$th-mode perturbation; otherwise it is unstable.

In case of a synchronous periodic orbit with period $p$, the Lyapunov exponent $\sigma_j$ in Eq. (4.14) becomes

$$\sigma_j = \frac{1}{p} \ln |\lambda_j|, \hspace{0.5cm} (4.15)$$

where $\lambda_j$, called the stability multiplier of the synchronous orbit, is given by

$$\lambda_j = \prod_{i=0}^{p-1} \left[u'(X_t^e) + \sum_{i=1}^{N} V^{(i)}(X_t^e) e^{2\pi i(l-1)/N}\right]. \hspace{0.5cm} (4.16)$$

The synchronous periodic orbit is stable against the $j$th-mode perturbation when $\lambda_j$ lies inside the unit circle, i.e., $|\lambda_j| < 1$. When the stability multiplier $\lambda_j$ increases through $1$, the synchronous periodic orbit loses its stability via saddle-node or pitchfork bifurcation. On the other hand, when $\lambda_j$ decreases through $1$, it becomes unstable via period-doubling bifurcation.

It follows from the coupling condition (4.3) that
\[ \sum_{i=1}^{N} V^{(i)}(X) = 0. \] (4.17)

Hence the Lyapunov exponent \( \sigma_0 \) becomes
\[ \sigma_0 = \lim_{m \to \infty} \frac{1}{m} \sum_{i=0}^{m-1} \ln |u'(X_i^*)|. \] (4.18)

It is just the Lyapunov exponent of the uncoupled 1D map. While there is no coupling effect on \( \sigma_0 \), coupling generally affects the other Lyapunov exponents \( \sigma_j \)'s \((j \neq 0)\).

In case of the global coupling of the form (4.5), the reduced coupling functions become
\[ V^{(l)}(X) = \begin{cases} (1-N)V(X), & \text{for } l = 1, \\ V(X), & \text{for } l \neq 1, \end{cases} \] (4.19)

where
\[ V(X) = \frac{c}{N} v'(X). \] (4.20)

Substituting \( V^{(l)} \)'s into Eq. (4.14), we obtain
\[ \sigma_j = \begin{cases} \lim_{m \to \infty} \frac{1}{m} \sum_{i=0}^{m-1} \ln |u'(X_i^*)| & \text{for } j = 0, \\ \lim_{m \to \infty} \frac{1}{m} \sum_{i=0}^{m-1} \ln \left|u'(X_i^*) - cr'(X_i^*)\right| & \text{for } j \neq 0. \end{cases} \] (4.21)

Here \( \sigma_0 \) is just the tangential Lyapunov exponent \( \sigma_0 \) of Eq. (3.54), characterizing the mean exponential rate of divergence of nearby orbits along the synchronization line (4.8). On the other hand, all the other ones \( \sigma_j \) \((j \neq 0)\) characterizing the mean exponential rate of divergence of nearby orbits across the synchronization line) are the same:
\[ \sigma_1 = \cdots = \sigma_{N-1} = \sigma_\perp. \] (4.22)

Consequently, there exists only one independent transversal Lyapunov exponent \( \sigma_\perp \), independently of \( N \).

As for the case of two-coupled maps in Sec. III C, we choose \( u(X) = 1 - AX^2 \) as the uncoupled 1D map, and consider a global-coupling case with \( r(X) = u(X) \), i.e., a global coupling of the form
\[ v(X_1, \ldots, X_N) = \frac{c}{N} \sum_{m=1}^{N} \left[ u(X(m)) - u(X(1)) \right] \text{ for } N \geq 2. \] (4.23)

[Here the case for \( N=2 \) is just the dissipative coupling of Eq. (3.46).] For this kind of global coupling, the independent transversal Lyapunov exponent \( \sigma_\perp \) is given by
\[ \sigma_\perp = \sigma_\perp + \ln |1 - c|, \] (4.24)

which is the same as that of Eq. (3.55) for the case \( N=2 \).

As in Sec. III C, we also consider the intermittency associated with a saddle-node bifurcation to a pair of synchronous periodic orbits with period 3. Then the phase diagram in Fig. 2 holds for all \( N (N \geq 2) \) globally coupled maps, because the two independent Lyapunov exponents \( \sigma_\parallel \) and \( \sigma_\perp \) are the same, irrespectively of \( N \). Consequently, there exists a critical line segment joining two ends \( c_1 = 0 \) and \( c_2 = 2 \) on the synchronous saddle-node-bifurcation line \( A = A_c = 1.75 \) in the \( c - A \) plane for any \( N \) globally coupled case. Thus, the critical behaviors near the critical line in any \( N \) globally coupled maps become the same as those in the two dissipatively coupled maps.

C. Renormalization analysis of many globally coupled maps

Following the same procedure of Sec. III for two coupled maps, we extend the renormalization results of two coupled maps to arbitrary \( N \) globally coupled maps. We thus find two fixed points of the reduced renormalization operator and obtain their relevant eigenvalues. These renormalization results are also confirmed for the case of a global coupling of the form (4.23), like the case of the two dissipatively coupled maps.

To study the intermittency in the vicinity of a saddle-node bifurcation to a pair of synchronous orbits with period 3, consider its \( p \)th iterate \( M^{(p)} \),
\[ M^{(p)};X_{t+1}(m) = W^{(p)}(\sigma^{m-1}X_i) = W^{(p)}(X_i(m),X_i(m+1),\ldots,X_i(m-1)), \] (4.25)

where \( W^{(p)} \) satisfies a recurrence relation
\[ W^{(p)}(X) = W(W^{(p-1)}(X),W^{(p-1)}(\sigma X),\ldots,\times W^{(p-1)}(\sigma^{N-1}X)), \] (4.26)

and it can be also decomposed into two parts, the uncoupled part \( u^{(p)} \) and the remaining coupling part, i.e.,
\[ W^{(p)}(X) = u^{(p)}(X(1)) + [W^{(p)}(X) - u^{(p)}(X(1))]. \] (4.27)

For the threshold value \( A_c \) of a synchronous saddle-node bifurcation, \( p \) synchronous fixed points of \( M^{(p)} \) appear. Shifting the origin of coordinates \( (X(1),\ldots,X(N)) \) to one of the \( p \) fixed points \( (X^*(1),\ldots,X^*(N)) \) \((X^*(1) = \cdots = X^*(N) = X^* = u^{(p)}(X^*) \) for \( A = A_c \), we have
\[ T:X_{t+1}(m) = F(\sigma^{m-1}X_i), \] (4.28)

where
\[ f(x(1)) = u^{(p)}(X(1)) - X^*, \] (4.29)
\[ g(x) = W^{(p)}(x(1) + X^*), \ldots,x(N) + X^*) - u^{(p)}(x(1) + X^*). \] (4.30)
Here \( x = (x_1, \ldots, x_N) \), the uncoupled part \( f \) for the critical case \( A = A_c \) satisfies the condition (3.7), and the coupling function also obeys the condition (4.3).

We employ the same renormalization transformation \( N \) of Eq. (3.9) with the rescaling operator \( aI \), where \( \alpha \) is a rescaling factor, and \( I \) is the \( N \times N \) identity matrix. Applying the renormalization operator \( N \) to the \( N \)-coupled map (4.28) \( n \) times, we obtain the \( n \)-times renormalized map \( T_n \) of the form

\[
T_n: x_{i+1}(m) = F_n(\sigma^{m-1} x_i)
\]

\[
= f_n(x_i(m)) + g_n(x_i(m), \ldots, x_i(m-1)), \tag{4.31}
\]

\( m = 1, \ldots, N. \)

Here the uncoupled and coupling parts \( f \) and \( g \) satisfy the following recurrence relations:

\[
f_{n+1}(x(1)) = \alpha f_n\left( f_n\left( \frac{x(1)}{\alpha} \right) \right), \tag{4.32}
\]

\[
g_{n+1}(x) = \alpha f_n\left( f_n\left( \frac{x}{\alpha} \right) \right) + \alpha g_n\left( f_n\left( \frac{x}{\alpha} \right), \ldots, f_n\left( \frac{x(1)}{\alpha} \right) \right), \tag{4.33}
\]

Then Eqs. (4.32) and (4.33) define a renormalization operator \( R \) of transforming a pair of functions \( (f, g) \):

\[
\begin{pmatrix} f_{n+1} \\ g_{n+1} \end{pmatrix} = R \begin{pmatrix} f_n \\ g_n \end{pmatrix}. \tag{4.34}
\]

A critical map \( T_c \) is attracted to a fixed map \( T^* \) under iterations of the renormalization transformation \( N \),

\[
T^*: x_{i+1}(m) = F^*(\sigma^{m-1} x_i)
\]

\[
= f^*(x_i(m)) + g^*(x_i(m), x_i(m+1), \ldots, x_i(m-1)), \tag{4.35}
\]

\( m = 1, \ldots, N. \)

Here \((f^*, g^*)\) is a fixed point of the renormalization operator \( R \), i.e., \((f^*, g^*) = R(f^*, g^*)\). Since \( f^* \) is just the 1D fixed map (3.16), only the equation for the coupling fixed function \( g^* \) is left to be solved.

As in case of two coupled maps, we construct a tractable recurrence equation for a reduced coupling function of \( g(x) \) defined by

\[
G^{(l)}(x) = \frac{\partial g(x)}{\partial x(l)} \bigg|_{x(1) = \cdots = x(N) = x}, \tag{4.36}
\]

because it is not easy to directly solve the equation for the coupling fixed function. Differentiating the recurrence equation (4.33) for \( g \) with respect to \( x(l) \) \( (l = 1, \ldots, N) \) and setting \( x(1) = \cdots = x(n) = x \), we obtain

\[
G^{(l)}(x) = f_n\left( f_n\left( \frac{x}{\alpha} \right) \right), \tag{4.37}
\]

The reduced coupling functions \( G^{(l)} \)’s satisfy the sum rule (4.17), i.e., \( \sum_{l=1}^N G^{(l)}(x) = 0 \), and they also satisfy \( G^{(l)}(x) = G^{(l+N)}(x) \) due to the periodic boundary condition.

As shown in Eq. (4.19), there exists only one independent reduced coupling function \( G(x) \) for the globally coupled case, such that

\[
G^{(1)} = \cdots = G^{(N)}(x) = G(x), \tag{4.38}
\]

Then it is easy to see that the successive images \( \{G^{(l)}(x)\} \) of \( \{G^{(1)}(x)\} \) under the transformation (4.37) also satisfy Eq. (4.38) [i.e., \( G^{(2)} = \cdots = G^{(N)}(x) = G(x), \quad G^{(1)}(x) = (1 - N)G(x) \)]. Consequently, there remains only one recurrence equation for the independent reduced coupling function \( G(x) \) [10]:

\[
G_{n+1}(x) = f_n\left( f_n\left( \frac{x}{\alpha} \right) \right) - NG_n\left( f_n\left( \frac{x}{\alpha} \right) \right) G_n\left( \frac{x}{\alpha} \right)
\]

\[
+ G_n f_n\left( \frac{x}{\alpha} \right) f_n\left( \frac{x}{\alpha} \right). \tag{4.39}
\]

Then, together with Eq. (4.32), Eq. (4.39) defines a reduced renormalization operator \( \tilde{R} \) of transforming a pair of functions \( (f, G) \):

\[
\begin{pmatrix} f_{n+1} \\ G_{n+1} \end{pmatrix} = \tilde{R} \begin{pmatrix} f_n \\ G_n \end{pmatrix}. \tag{4.40}
\]

Since the reduced renormalization transformation (4.40) holds for any globally coupled cases of \( N \geq 2 \), it can be regarded as a generalized version of Eq. (3.20) for the case of two coupled maps.

A pair of critical functions \((f_c, G_c)\) with the parameters set to their critical values is attracted to a fixed point \((f^*, G^*)\) under iterations of \( \tilde{R} \). Here \( f^* \) is the 1D fixed map (3.16), and \( G^*(x) \) is the independent reduced coupling fixed function of \((f^*, G^*)\) [i.e., \( G^*(2^0(x)) = \cdots = G^*(N)(x) = G^*(x), \quad G^*(1)(x) = (1 - N)G^*(x) \)]. As in the two-coupled case \((N = 2)\) of Eqs. (3.21) and (3.22), we find two series solutions for \( G^* \):

\[
G^*_f(x) = \frac{1}{N}\left[1 + az x^{2^{l-1} - 1} + (z - 1)^{2} a^2 x^{2^{l-1} + 1} + \cdots \right], \tag{4.41}
\]

\[
G^*_h(x) = \frac{1}{N}\left[ b x^{2^{l-1} - 1} + \left( \frac{3z - 1}{2} \right) a^2 x^{2^{l-1} + 1} + \cdots \right]. \tag{4.42}
\]
Here $a$ and $b$ are arbitrary constants. The solutions for $G^*$ have a common factor $1/N$, and hence the function $N G^*(x)$ becomes the same, independently of $N$; this can be also easily understood by looking at the structure of Eq. (4.39). In case of $G^*_I(x)$, we can sum the series and obtain a closed-form solution,

$$ G^*_I(x) = \frac{1}{N} f^*_{-1}(x). \quad (4.43) $$

However, unfortunately we cannot sum the series in $G^*_H(x)$ except for the cases $b=0$ and $z$ where we obtain closed-form solutions,

$$ G^*_H(x) = \begin{cases} 
0, & \text{for } b=0, \\
\frac{1}{N} [f^*_{-1}(x) - 1], & \text{for } b=z. 
\end{cases} \quad (4.44) $$

Once a fixed point ($f^*, g^*$) of the renormalization operator $R$ is determined, its eigenvalues are obtained by linearizing $R$ at the fixed point and solving the resultant eigenvalue problem. As shown in Sec. III B, the eigenvalues are possibly obtained using the independent reduced coupling fixed function $G^*$ rather than $g^*$, because all eigenvalues of the reduced eigenvalue equation are also eigenvalues of the original eigenvalue equation. Note also that the reduced eigenvalue equation can be obtained by directly linearizing the reduced renormalization operator $\bar{R}$ at its fixed point. We thus linearize $\bar{R}$ at its fixed point ($f^*, G^*$) and obtain a reduced linearized operator $\bar{L}$ transforming a pair of infinitesimal perturbations $(h, \Phi)$:

$$ \begin{pmatrix} h_{n+1} \\
\Phi_{n+1} 
\end{pmatrix} = \bar{L} \begin{pmatrix} h_n \\
\Phi_n 
\end{pmatrix} = \begin{pmatrix} L_1 & 0 \\
L_3 & \bar{L}_2 
\end{pmatrix} \begin{pmatrix} h_n \\
\Phi_n 
\end{pmatrix}, \quad (4.45) $$

where

$$ h_{n+1}(x) = [L_1 h_n(x)](x) = a f^* \left( f^* \left( \frac{x}{\alpha} \right) \right) h_n \left( \frac{x}{\alpha} \right) + a h_n \left( f^* \left( \frac{x}{\alpha} \right) \right), \quad (4.46) $$

$$ \Phi_{n+1}(x) = [\bar{L}_2 \Phi_n(x)](x) + [\bar{L}_3 h_n(x), \quad (4.47) $$

$$ [\bar{L}_2 \Phi_n(x)](x) = \left[ f^* \left( f^* \left( \frac{x}{\alpha} \right) \right) - N G^* \left( f^* \left( \frac{x}{\alpha} \right) \right) \right] \Phi_n \left( \frac{x}{\alpha} \right) $$

$$ + \left[ f^* \left( \frac{x}{\alpha} \right) - N G^* \left( \frac{x}{\alpha} \right) \right] \Phi_n \left( \frac{x}{\alpha} \right), \quad (4.48) $$

It follows from the reducibility of $\tilde{L}$ into a semiblock form that to determine the eigenvalues of $\tilde{L}$ it is sufficient to solve the eigenvalue problems for $L_1$ and $\bar{L}_2$ independently. Then the eigenvalues of both $L_1$ and $\bar{L}_2$ give the whole spectrum of $\tilde{L}$.

The eigenvalue equation for $L_1$ is given by Eq. (3.31). As mentioned there, that is just the eigenvalue equation for the 1D map, in which case the complete spectrum of eigenvalues and the corresponding eigenfunctions have been found in Refs. [3].

We next consider an infinitesimal coupling perturbation of the form $(0, \Phi)$ to a fixed point $(f^*, G^*)$. If an independent reduced coupling perturbation $\Phi^*$ satisfies

$$ \lambda \Phi^*(x) = [\bar{L}_2 \Phi^*(x)](x) $$

$$ = \left[ f^* \left( f^* \left( \frac{x}{\alpha} \right) \right) - N G^* \left( f^* \left( \frac{x}{\alpha} \right) \right) \right] \Phi^* \left( \frac{x}{\alpha} \right) $$

$$ + \left[ f^* \left( \frac{x}{\alpha} \right) - N G^* \left( \frac{x}{\alpha} \right) \right] \Phi^* \left( \frac{x}{\alpha} \right), \quad (4.50) $$

then it is called the independent reduced coupling eigenfunction with CE $\lambda$. Note that the eigenvalue equation (4.50) for any $N$ becomes the same as that for the two-coupled case ($N=2$), because the function $NG^*(x)$ is the same, irrespectively of $N$. Hence we follow the same procedure in Sec. III B for two coupled maps, and find the same relevant CE’s for any $N$ globally coupled maps as follows (for more details, refer to Sec. III B):

$$ (1) G^*(x) = G^*_I(x), $$

there exist no relevant CE’s;

$$ (2) G^*(x) = G^*_H(x), \quad (4.41) $$

there exist $(z-1)$ relevant CE’s such that $\lambda_k = 2^{(z-1-k)/(z-1)}$ with eigenfunction $\Phi^*_k(x)$ of Eq. (3.42)

$$ (k=0, \ldots, z-2). \quad (4.42) $$

Finally, we confirm the above renormalization results for the case of a global coupling of Eq. (4.23). As an example, we study the intermittency associated with a saddle-node bifurcation to a pair of synchronous orbits with period $p=3$. Considering the third iterate $M^{(3)}$ of $M$ [see Eq. (4.25)] and
then shifting the origin of coordinates to one of the three synchronously fixed points for $A=A_c$, we obtain a map $T$ of the form (4.28). The uncoupled part $f$ has the form (3.49), and hence that corresponds to the most common case with the tangency order $z=2$. The independent reduced coupling function of the coupling part $g(x)$ is also given by

$$G(x) = \frac{e}{N} f'(x), \quad e = c^3 - 3c^2 + 3c. \quad (4.53)$$

Consider a pair of initial functions $(f_e, G)$ on the synchronous saddle-node bifurcation line $A=A_c$, where $f_e(x)$ is just the 1D critical map and $G(x) = (e/N)f'(x)$. By successive applications of the reduced renormalization operator $\hat{R}$ of Eq. (4.40) to $(f_e, G)$, we have

$$f_n(x) = \alpha f_{n-1}\left(f_{n-1}\left(\frac{x}{\alpha}\right)\right), \quad G_n(x) = \frac{e_n}{N} f_0'(x) \quad (4.54)$$

$$e_n = 2e_{n-1} - e_{n-1}^2 \quad (n = 0, 1, 2, \ldots), \quad (4.55)$$

where the rescaling factor for $z=2$ is $\alpha=2$, $f_0(x) = f_0(x)$, $G_0(x) = G(x)$, and $e_0 = e$. Here $f_n$ converge to the 1D fixed function $f^*(x)$ of Eq. (3.16) with $z=2$ as $n \to \infty$.

Note that the recurrence relation (4.55) for $e$ is the same as that of Eq. (3.52) for the dissipatively coupled case in Sec. III C. As shown there, any initial $e$ inside the open interval $(0,2)$ converges to the superstable fixed point $e^* = 1$ under successive iterations of the transformation (4.55). The left end of the interval is an unstable fixed point $e^*=0$, which is also the image of the right end $e = 2$ under the transformation (4.55); all the other points outside the interval diverges to the minus infinity under iterations of the transformation (4.55). One can see easily that the interval $[0,2]$ of the parameter $e$ corresponds to a critical line segment joining two ends $c_t = 0$ and $c_r = 2$ on the synchronous saddle-node bifurcation line $A=A_c$ in the $e$-$A$ plane. Hence any initial $G(x)$ inside the critical line segment is attracted to the first independent reduced coupling fixed function $G^*_r(x) = (1/N)f^*(x)$ (corresponding to $e^* = 1$) under iterations of $\hat{R}$, while $G(x)$’s at both ends are attracted to the second independent reduced coupling fixed function $G^*_l(x) = 0$ with $b = 0$ (corresponding to $e^* = 0$). Consequently, the critical behaviors inside the critical line are governed by the first fixed point $(f^*, G^*_r)$ with no relevant CE’s, while the second fixed point $(f^*, G^*_l)$ governs the critical behaviors at both ends of the critical line. For details on the critical behaviors governed by the two fixed points, refer to the $N=2$ case in Sec. III C, because the critical behaviors for any $N$ globally coupled case become the same as those for the two-coupled case.

V. SUMMARY

The critical behaviors for intermittency in two-coupled 1D maps are studied by a reduced renormalization method. We thus find two fixed points of the reduced renormalization operator. Although they have common relevant eigenvalues associated with scaling of the control parameter of the uncoupled 1D map, their relevant CE’s associated with coupling perturbations may vary depending on the fixed points. We also study the intermittency for a dissipative-coupling case and confirm the renormalization results. Two fixed points are found to be associated with the critical behaviors near a critical line segment. One fixed point with no relevant CE’s governs the critical behaviors inside the critical line, associated with the 1D-like intermittent transition to chaos occurring on the synchronization line. On the other hand, the other fixed point with relevant CE’s governs the critical behaviors at both ends of the critical line, where the 1D-like intermittent transition to chaos ends due to the system desynchronization. Note that this kind of critical behaviors near a critical line are also found for a linearly coupled case [15]. Finally, the results of the two-coupled 1D maps are also extended to many globally coupled 1D maps.
